Build Infrastructure

With Terraform installed, you are ready to create your first infrastructure.

In this tutorial, you will provision an EC2 instance on Amazon Web Services (AWS). EC2 instances are virtual machines running on AWS, and a common component of many infrastructure projects.

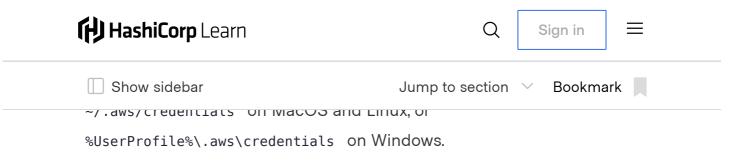

Prerequisites

To follow this tutorial you will need:

• The Terraform CLI (0.14.9+) installed.

- The AWS CLI installed.
- An AWS account.
- Your AWS credentials. You can create a new Access Key on this page.

Configure the AWS CLI from your terminal. Follow the prompts to input your AWS Access Key ID and Secret Access Key.

Note: This tutorial will provision resources that qualify under the AWS free tier. We are not responsible for any charges that you may incur.

» Write configuration

The set of files used to describe infrastructure in Terraform is known as a Terraform *configuration*. You will write your first configuration to define a single AWS EC2 instance.

Each Terraform configuration must be in its own working directory. Create a directory for your configuration.

\$ mkdir learn-terraform-aws-instance
Copy Copy

Change into the directory.

\$ cd learn-terraform-aws-instance Copy

Create a file to define your infrastructure.

```
$ touch main.tf Copy
```

Open main.tf in your text editor, paste in the configuration below, and save the file.

Tip: The AMI ID used in this configuration is specific to the us-west-2 region. If you would like to use a different region, see the Troubleshooting section for guidance.

```
terraform {
                                                           Copy 🚉
  required providers {
    aws = {
      source = "hashicorp/aws"
      version = "~> 3.27"
    }
  }
  required version = ">= 0.14.9"
}
provider "aws" {
  profile = "default"
  region = "us-west-2"
}
resource "aws_instance" "app_server" {
                = "ami-830c94e3"
  instance_type = "t2.micro"
  tags = {
    Name = "ExampleAppServerInstance"
  }
}
```

This is a complete configuration that you can deploy with Terraform. The following sections review each block of this configuration in more detail.

Terraform Block

The terraform {} block contains Terraform settings, including the required providers Terraform will use to provision your infrastructure. For each provider, the source attribute defines an optional hostname, a namespace, and the provider type. Terraform installs providers from the Terraform Registry by default. In this example configuration, the aws provider's source is defined as hashicorp/aws, which is shorthand for registry.terraform.io/hashicorp/aws.

You can also set a version constraint for each provider defined in the required_providers block. The version attribute is optional, but we recommend using it to constrain the provider version so that Terraform does not install a version of the provider that does not work with your configuration. If you do not specify a provider version, Terraform will automatically download the most recent version during initialization.

To learn more, reference the provider source documentation.

Providers

The provider block configures the specified provider, in this case aws. A provider is a plugin that Terraform uses to create and manage your resources.

The profile attribute in the aws provider block refers Terraform to the AWS credentials stored in your AWS configuration file, which you created when you configured the AWS CLI. Never hard-code credentials or other secrets in your Terraform configuration files. Like other types of code, you may share and manage your Terraform configuration files using source control, so hard-coding secret values can expose them to attackers.

You can use multiple provider blocks in your Terraform configuration to manage resources from different providers. You can even use different providers together. For example, you could pass the IP address of your AWS EC2 instance to a monitoring resource from DataDog.

Resources

Use resource blocks to define components of your infrastructure. A resource might be a physical or virtual component such as an EC2 instance, or it can be a logical resource such as a Heroku application.

Resource blocks have two strings before the block: the resource type and the resource name. In this example, the resource type is <code>aws_instance</code> and the name is <code>app_server</code>. The prefix of the type maps to the name of the provider. In the example configuration, Terraform manages the <code>aws_instance</code> resource with the <code>aws</code> provider. Together, the resource type and resource name form a unique ID for the resource. For example, the ID for your EC2 instance is <code>aws_instance.app_server</code>.

Resource blocks contain arguments which you use to configure the resource. Arguments can include things like machine sizes, disk image names, or VPC IDs. Our providers reference documents the required and optional arguments for each resource. For your EC2 instance, the example configuration sets the AMI ID to an Ubuntu image, and the instance type to t2.micro, which qualifies for AWS' free tier. It also sets a tag to give the instance a name.

Initialize the directory

When you create a new configuration — or check out an existing configuration from version control — you need to initialize the directory with terraform init.

Initializing a configuration directory downloads and installs the providers defined in the configuration, which in this case is the aws provider.

Initialize the directory.

\$ terraform init Copy 🖹

Initializing the backend...

Initializing provider plugins...

- Finding hashicorp/aws versions matching "~> 3.27"...
- Installing hashicorp/aws v3.27.0...
- Installed hashicorp/aws v3.27.0 (signed by HashiCorp)

Terraform has created a lock file .terraform.lock.hcl to record the selections it made above. Include this file in your version control so that Terraform can guarantee to make the same selections by defayou run "terraform init" in the future.

Terraform has been successfully initialized!

You may now begin working with Terraform. Try running "terraform pl any changes that are required for your infrastructure. All Terrafor should now work.

If you ever set or change modules or backend configuration for Terr rerun this command to reinitialize your working directory. If you 1 commands will detect it and remind you to do so if necessary.

Terraform downloads the aws provider and installs it in a hidden subdirectory of your current working directory, named .terraform .The terraform init command prints out which version of the provider was installed. Terraform also creates a lock file named .terraform.lock.hcl which specifies the exact provider versions used, so that you can control when you want to update the providers used for your project.

Format and validate the configuration

We recommend using consistent formatting in all of your configuration files. The terraform fmt command automatically updates configurations in the current directory for readability and consistency.

Format your configuration. Terraform will print out the names of the files it modified, if any. In this case, your configuration file was already formatted correctly, so Terraform won't return any file names.

\$ terraform fmt Copy

You can also make sure your configuration is syntactically valid and internally consistent by using the terraform validate command.

Validate your configuration. The example configuration provided above is valid, so Terraform will return a success message.

\$ terraform validate Copy 🖺
Success! The configuration is valid.

Create infrastructure

Apply the configuration now with the terraform apply command.

Terraform will print output similar to what is shown below. We have truncated some of the output to save space.

\$ terraform apply

An execution plan has been generated and is shown below.

Resource actions are indicated with the following symbols:

+ create

Terraform will perform the following actions:

aws_instance.app_server will be created

+ resource "aws_instance" "app_server" {

Tip: If your configuration fails to apply, you may have customized your region or removed your default VPC. Refer to the troubleshooting section at the bottom of this tutorial for help.

Before it applies any changes, Terraform prints out the *execution plan* which describes the actions Terraform will take in order to change your infrastructure to match the configuration.

The output format is similar to the diff format generated by tools such as Git. The output has a + next to aws_instance.app_server, meaning that Terraform will create this resource. Beneath that, it shows the attributes that will be set. When the value displayed is (known after apply), it means that the value will not be known until the resource is created. For example, AWS assigns Amazon Resource Names (ARNs) to instances upon creation, so Terraform cannot know the value of the arn attribute until you apply the change and the AWS provider returns that value from the AWS API.

Terraform will now pause and wait for your approval before proceeding. If anything in the plan seems incorrect or dangerous, it is safe to abort here with no changes made to your infrastructure.

In this case the plan is acceptable, so type yes at the confirmation prompt to proceed. Executing the plan will take a few minutes since Terraform waits for the EC2 instance to become available.

```
Enter a value: yes

aws_instance.app_server: Creating...
aws_instance.app_server: Still creating... [10s elapsed]
aws_instance.app_server: Still creating... [20s elapsed]
aws_instance.app_server: Still creating... [30s elapsed]
aws_instance.app_server: Creation complete after 36s [id=i-01e03375]
Apply complete! Resources: 1 added, 0 changed, 0 destroyed.
```

You have now created infrastructure using Terraform! Visit the EC2 console and find your new EC2 instance.

Note: Per the aws provider block, your instance was created in the us-west-2 region. Ensure that your AWS Console is set to this region.

Inspect state

When you applied your configuration, Terraform wrote data into a file called terraform.tfstate. Terraform stores the IDs and properties of the resources it manages in this file, so that it can update or destroy those resources going forward.

The Terraform state file is the only way Terraform can track which resources it manages, and often contains sensitive information, so you must store your state file securely and restrict access to only trusted team members who need to manage your infrastructure. In production, we recommend storing your state remotely with Terraform Cloud or

Terraform Enterprise. Terraform also supports several other remote backends you can use to store and manage your state.

Inspect the current state using terraform show.

```
$ terraform show
                                                          Copy 🚉
# aws instance.app server:
resource "aws instance" "app server" {
    ami
                                 = "ami-830c94e3"
                                 = "arn:aws:ec2:us-west-2:561656986
    arn
    associate public ip address = true
    availability zone
                                 = "us-west-2c"
    cpu core count
                                 = 1
    cpu threads per core
                                 = 1
    disable api termination
                               = false
    ebs optimized
                                 = false
    get password data
                                 = false
    hibernation
                                 = false
    id
                                 = "i-01e03375ba238b384"
    instance state
                                 = "runnina"
                                 = "t2.micro"
    instance type
    ipv6_address_count
                                 = 0
    ipv6 addresses
                                 = []
    monitoring
                                 = false
    primary network interface id = "eni-068d850de6a4321b7"
    private dns
                                 = "ip-172-31-0-139.us-west-2.compu
                                 = "172.31.0.139"
    private_ip
                                 = "ec2-18-237-201-188.us-west-2.cc
    public dns
                                 = "18.237.201.188"
    public ip
    secondary private ips
                                 = []
    security_groups
                                 = [
        "default",
    1
    source dest check
                                 = true
    subnet id
                                 = "subnet-31855d6c"
    tags
        "Name" = "ExampleAppServerInstance"
    }
    tenancy
                                 = "default"
```

```
vpc_security_group_ids
    "sg-0edc8a5a",
                          = [
]
credit specification {
    cpu credits = "standard"
}
enclave options {
    enabled = false
}
metadata options {
                                 = "enabled"
    http endpoint
    http_put_response_hop_limit = 1
    http tokens
                                  = "optional"
}
root block device {
    delete on termination = true
    device name
                           = "/dev/sda1"
    encrypted
                           = false
                           = 0
    iops
    tags
                           = {}
    throughput
                           = 0
    volume id
                           = "vol-031d56cc45ea4a245"
    volume_size
                           = 8
    volume_type
                           = "standard"
}
```

When Terraform created this EC2 instance, it also gathered the resource's metadata from the from the AWS provider and wrote the metadata to the state file. Later in this collection, you will modify your configuration to reference these values to configure other resources and output values.

Manually Managing State

Terraform has a built-in command called terraform state for advanced state management. Use the list subcommand to list of the resources in your project's state.

```
$ terraform state list

aws instance.app server
```

Troubleshooting

If terraform validate was successful and your apply still failed, you may be encountering one of these common errors.

- If you use a region other than us-west-2, you will also need to change your ami, since AMI IDs are region-specific. Choose an AMI ID specific to your region by following these instructions, and modify main.tf with this ID. Then re-run terraform apply.
- If you do not have a default VPC in your AWS account in the correct region, navigate to the AWS VPC Dashboard in the web UI, create a new VPC in your region, and associate a subnet and security group to that VPC. Then add the security group ID (vpc_security_group_ids) and subnet ID (subnet_id) arguments to your aws_instance resource, and replace the values with the ones from your new security group and subnet.

Save the changes to main.tf, and re-run terraform apply.

Remember to add these lines to your configuration for the rest of the tutorials in this collection. For more information, review this document from AWS on working with VPCs.

Next Steps

Now that you have created your first infrastructure using Terraform, continue to the next tutorial to modify your infrastructure.

For more detail on the concepts used in this tutorial:

- Read about the Terraform configuration language in the Terraform documentation.
- Learn more about Terraform providers.
- Find examples of other uses for Terraform in the documentation use cases section.
- Read the AWS provider documentation to learn more about AWS authentication.
- For more information about the terraform state command and subcommands for moving or removing resources from state, see the CLI state command documentation.
